Today

Announcements

- homework 5 due Friday at 5p

Recap

- reliable data transport over channels with errors and loss

Pipelined protocols

- go-back-N
- selective repeat
- sequence numbers in practice

Reliable Data Transport

CHANNELS WITH ERROR AND LOSS

rdt3.0: channels with errors and loss

Problems

- underlying channel may flip bits in packet
 - both data and ACKs may be garbled
- underlying channel can also lose packets
 - both data and ACKs
- checksum, seq. #, ACKs, retransmissions will be of help
 - ... but not enough

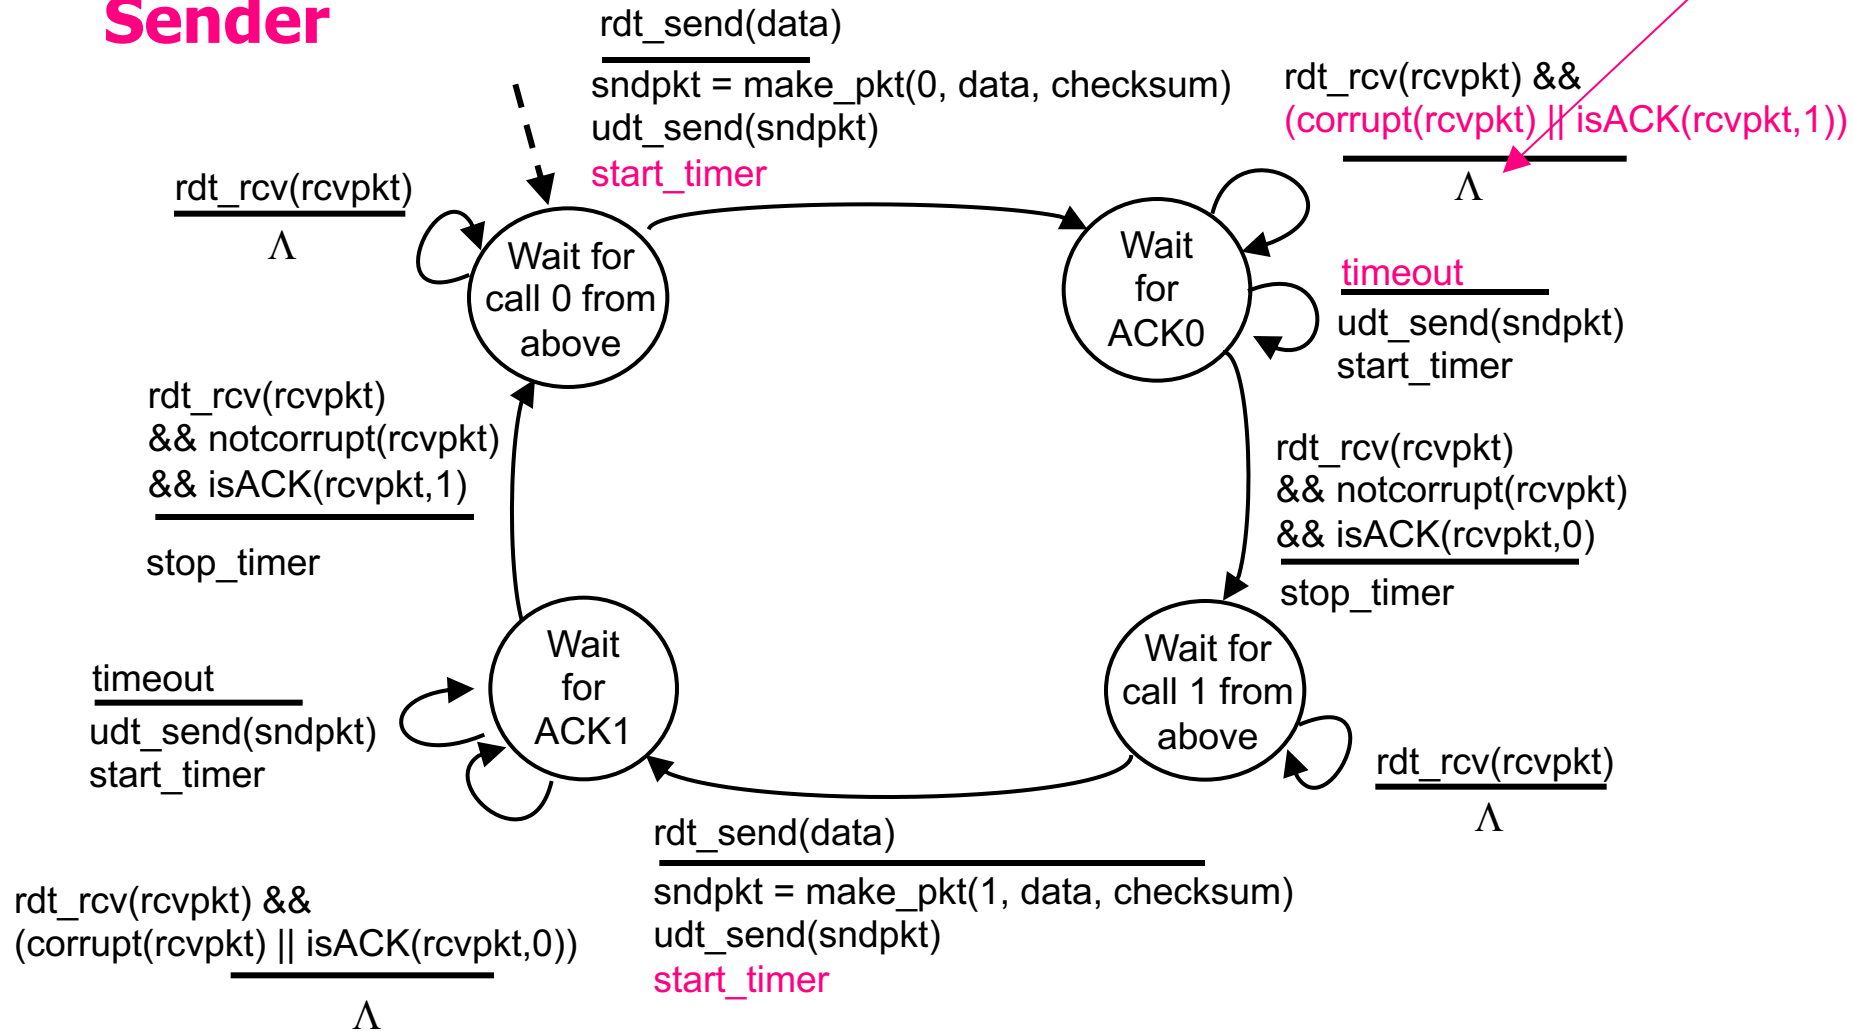

Solution: add countdown timer

- sender **waits** “reasonable” amount of time for ACK
 - retransmits if no ACK received in this time
- if pkt (or ACK) just **delayed** (not lost)
 - retransmission will be duplicate, but seq #'s already handles this
- receiver must specify **seq # of pkt being ACKed**

rdt3.0 sender

Why do nothing ? Why not resend pkt0? Because sender doesn't know whether ack1 means pkt 0 garbled or pkt 1 duplicate received
By not resending pkt 0, sender doesn't introduce potentially unnecessary (even if valid) traffic: saves bandwidth

Sender

rdt3.0 in action

(a) no loss

(b) packet loss

rdt3.0 in action

(c) ACK loss

(d) premature timeout/ delayed ACK

Reliable Data Transport

PIPELINED PROTOCOLS

rdt3.0: stop-and-wait operation

$$U_{\text{sender}} = \frac{\text{Time spent sending stuff } L / R}{\text{Total time } RTT + L / R} = \frac{.008}{30.008} = 0.00027$$

Problem: how to maintain high link utilization?

Get rid of stop-and wait

Use pipelining (aka sliding-window protocols), like in HTTP

- sender allows multiple, in-flight, yet-to-be-acknowledged pkts
 - send up to **N packets** at a time, unacked
 - **range of seq #s** must be increased
 - sender **needs more memory** to buffer outstanding unacked packets

Achieves higher link utilization than stop-and-wait!

Increased utilization with pipelining

3-packet pipelining

$$U_{\text{sender}} = \frac{\text{Time spent sending stuff}}{\text{Total time}} = \frac{3L / R}{RTT + L / R} = \frac{.0024}{30.008} = 0.00081$$

3-packet pipelining
increases utilization by
factor of 3!

Pipelined protocols

Send N packets without receiving ACKs. How to ACK now?

Cumulative ACKs: Go-Back-N protocol

- **sender**
 - has timer for **oldest unacked pkt**
 - when timer expires: **retransmit all unacked pkts**
 - pkts received correctly may be retransmitted
- **receiver** only sends cumulative ack, doesn't ack pkt if gap

Selective ACKs: Selective Repeat protocol

- **sender**
 - has timer for **each unacked pkt**
 - when timer expires, **retransmit only unacked pkt**
 - only corrupted/lost pkts are retransmitted
- **receiver** sends individual ack for each pkt

How pipelining protocols work

Use sliding window

- how sender keeps track of what it can send
- **window**: set of N adjacent seq #s
 - only send packets in window

If window large enough, will fully utilize link

Pipelined Protocols

GO-BACK-N

Go-Back-N: sender

Window of up N consecutive unacked pkts allowed

- ACK(n) is **cumulative ACK**
 - ACKs all pkts up to, including seq # n
 - may receive duplicate ACKs (see receiver)
- timer for **oldest in-flight pkt**
 - timeout(n): retransmit packet n and all higher seq # pkts in window

Go-Back-N: sender FSM

rdt_send(data)

```
if (nextseqnum < base+N) {  
    sndpkt[nextseqnum] = make_pkt(nextseqnum,data,chksum)  
    udt_send(sndpkt[nextseqnum])  
    if (base == nextseqnum)  
        start_timer  
    nextseqnum++  
}  
else refuse_data(data)
```

**Send as long as pkt
within window**

Λ
base=1
nextseqnum=1

Ignore corrupt

rdt_rcv(rcvpkt) && corrupt(rcvpkt)

Λ

**Resend up to
nextseqnum on
timeout**

timeout

```
start_timer  
udt_send(sndpkt[base])  
udt_send(sndpkt[base+1])  
...  
udt_send(sndpkt[nextseqnum-1])
```

rdt_rcv(rcvpkt) &&
notcorrupt(rcvpkt)

base = getacknum(rcvpkt)+1

If (base == nextseqnum)

stop_timer

else

start_timer

**Cumulative ack: move
base to ack# + 1**

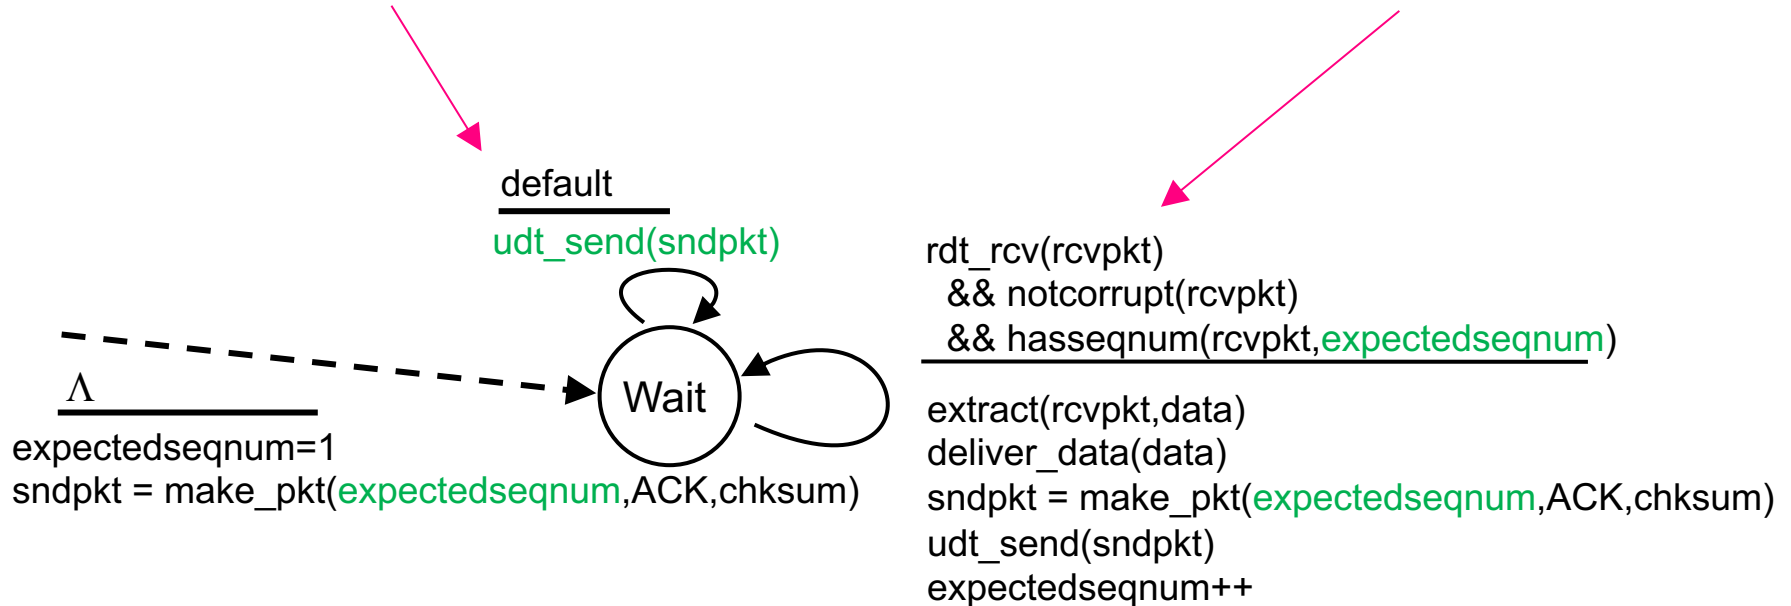

Go-Back-N: receiver FSM

Out-of-order pkt and all other cases

- discard: no receiver buffering!
- re-ACK pkt with highest in-order seq #

Correct pkt with highest in-order seq

- send ACK, may be duplicate ACK
- need only remember expectedseqnum

Retransmit window size worth of packets for 1 error

large window size $\Rightarrow$ large delays

Go-Back-N in action

sender window (N=4)

0 1 2 3 4 5 6 7 8
0 1 2 3 4 5 6 7 8
0 1 2 3 4 5 6 7 8
0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8
0 1 2 3 4 5 6 7 8

0 1 2 3 4 5 6 7 8
0 1 2 3 4 5 6 7 8
0 1 2 3 4 5 6 7 8

send pkt3
send pkt4
send pkt5

receiver

receive pkt0, send ack0
receive pkt1, send ack1

receive pkt3, discard,
(re)send ack1

receive pkt4, discard,
(re)send ack1

receive pkt5, discard,
(re)send ack1

rcv pkt2, deliver, send ack2
rcv pkt3, deliver, send ack3
rcv pkt4, deliver, send ack4
rcv pkt5, deliver, send ack5

X loss

Go-Back-N summary

Pros

- no receiver buffering
 - saves resources by requiring packets to arrive in-order
 - avoids large bursts of packet delivery to higher layers
- simpler buffering & protocol processing
 - can easily detect duplicates if out-of-sequence packet is received

Cons

- wastes capacity
 - on timeout for packet N sender retransmits from N all over again (all outstanding packets) including potentially correctly received packets

Tradeoff: buffering/processing complexity vs. capacity
(time vs. space)

Pipelined Protocols

SELECTIVE REPEAT

Selective repeat

Rather than ACK cumulatively, ACKs selectively

Receiver

- individually ACKs all correctly received pkts
- buffers pkts, as needed, for eventual in-order delivery to upper layer

Sender

- only resends pkts for which ACK not received
- sender timer for each unACKed pkt

Sender window

- N consecutive seq #s
- limits seq #s of sent, unACKed pkts

Selective repeat: sender, receiver windows

Selective repeat sender

Event: data from above

- action: if has next available seq # in window, send packet, start timer

Event: timeout(n)

- action: resend packet n, restart timer

Event: ACK(n) in [sendbase, sendbase + N]

- action
 - mark packet n as received
 - if n is smallest unACKed packet
 - advance window base to next unACKed seq #

Selective repeat receiver

Event: pkt n in $[rcvbase, rcvbase+N-1]$

– action:

- send ACK(n)
- out-of-order
 - buffer
- in-order
 - deliver (also deliver buffered, in-order pkts)
 - advance window to next not-yet-received pkt

Event: pkt n in $[rcvbase-N, rcvbase-1]$

– action: send ACK(n)

Event: otherwise

– action: ignore

Selective repeat in action

sender window (N=4)

receive pkt3, buffer, send ack3

receive pkt4, buffer, send ack4

receive pkt5, buffer, send ack5

receive pkt2
deliver pkt2, pkt3, pkt4, pkt5
send ack2

*Q: what happens
when ack2 arrives?*

Selective repeat: dilemma

Example

- seq #'s: 0, 1, 2, 3 and window size=3

Selective repeat: dilemma

Example

- seq #'s: 0, 1, 2, 3 and window size=3

Problem: duplicate data accepted as new:
receiver sees no difference in two scenarios!

Q: what is relationship between seq # size and window size to avoid problem in (b)?

Selective repeat summary

Q: When is selective repeat useful?

When channel generates errors frequently

Pros

- more efficient capacity use
 - only retransmit missing packets

Cons

- receiver buffering
 - to store out-of-order packets
- more complicated buffering & protocol processing
 - to keep track of missing out-of-order packets

Tradeoff again between buffering/processing
complexity and capacity

Sequence numbers

HOW USED IN PRACTICE

Sequence #s in practice

How large must seq # space be?

- depends on window size

Example

- seq # space = $[0, 2^4-1]$
- window size = 8

Solution: seq # space must be large enough to cover both sender + receiver windows. I.e., $\geq 2 \times \text{window size}$

Sequence #s in practice

What are they counting?

- bytes, not packets
 - sending packets but counting bytes
 - so seq #s do not increase incrementally

Sequence # space

- finite
 - e.g., 32 bits so 0 to $2^{32}-1$ values
 - must wrap around to 0 when hit max seq #
- TCP initial seq # is randomly chosen from space of values
 - security (harder to spoof)
 - to prevent confusing segments from different connections
 - different operating systems set differently: can fingerprint machines
