Today

1. Distance vector routing
2. Internet routing
 - overview
3. Internet Control Message Protocol (ICMP)

Control Plane

DISTANCE VECTOR ROUTING

Distance vector algorithm run at each node x

Initialization

For all **dst** $y \in N$
if y is nbr of x
 $D_x(y) = c(x, y)$
else
 $D_x(y) = \infty$

For each **nbr** w and **dst** $y \in N$
 $D_w(y) = \infty$

Send x 's DV to all nbrs w
 $D_x = [D_x(y) : y \in N]$

Loop

x *waits* for change in local link cost or DV msg from neighbor

recompute estimates

$$D_x(y) = \min_v \{ c(x, v) + D_v(y) \}$$

if x 's DV to any dst has changed, *notify* neighbors

Q: when does loop terminate?
When no more changes

$$D_x(y) = \min\{c(x,y)+D_y(y), c(x,z)+D_z(y)\}$$

$$= \min\{2+0, 7+1\} = 2$$

$$D_x(z) = \min\{c(x,y)+D_y(z), c(x,z)+D_z(z)\}$$

$$= \min\{2+1, 7+0\} = 3$$

Node x

		cost to		
		x	y	z
from	x	0	2	7
	y	∞	∞	∞
	z	∞	∞	∞

		cost to		
		x	y	z
from	x	0	2	3
	y	2	0	1
	z	7	1	0

Node y

		cost to		
		x	y	z
from	x	∞	∞	∞
	y	2	0	1
	z	∞	∞	∞

Node z

		cost to		
		x	y	z
from	x	∞	∞	∞
	y	∞	∞	∞
	z	7	1	0

$$D_x(y) = \min\{c(x,y)+D_y(y), c(x,z)+D_z(y)\}$$

$$= \min\{2+0, 7+1\} = 2$$

$$D_x(z) = \min\{c(x,y)+D_y(z), c(x,z)+D_z(z)\}$$

$$= \min\{2+1, 7+0\} = 3$$

Node x

		cost to		
		x	y	z
from	x	0	2	7
	y	∞	∞	∞
	z	∞	∞	∞

		cost to		
		x	y	z
from	x	0	2	3
	y	2	0	1
	z	7	1	0

Node y

		cost to		
		x	y	z
from	x	∞	∞	∞
	y	2	0	1
	z	∞	∞	∞

		cost to		
		x	y	z
from	x	0	2	7
	y	2	0	1
	z	7	1	0

Node z

		cost to		
		x	y	z
from	x	∞	∞	∞
	y	∞	∞	∞
	z	7	1	0

		cost to		
		x	y	z
from	x	0	2	7
	y	2	0	1
	z	3	1	0

$$D_z(x) = \min\{c(z,x)+D_x(x), c(z,y)+D_y(x)\}$$

$$= \min\{7+0, 1+2\} = 3$$

Node x

cost to

	x	y	z
from x	0	2	7
from y	∞	∞	∞
from z	∞	∞	∞

cost to

	x	y	z
from x	0	2	3
from y	2	0	1
from z	7	1	0

cost to

	x	y	z
from x	0	2	3
from y	2	0	1
from z	3	1	0

Node y

cost to

	x	y	z
from x	∞	∞	∞
from y	2	0	1
from z	∞	∞	∞

cost to

	x	y	z
from x	0	2	3
from y	2	0	1
from z	3	1	0

No change:
don't send
out DV

cost to

	x	y	z
from x	0	2	3
from y	2	0	1
from z	3	1	0

Node z

cost to

	x	y	z
from x	∞	∞	∞
from y	∞	∞	∞
from z	7	1	0

cost to

	x	y	z
from x	0	2	7
from y	2	0	1
from z	3	1	0

cost to

	x	y	z
from x	0	2	3
from y	2	0	1
from z	3	1	0

Node x

cost to

	x	y	z
from x	0	2	7
from y	∞	∞	∞
from z	∞	∞	∞

cost to

	x	y	z
from x	0	2	3
from y	2	0	1
from z	7	1	0

cost to

	x	y	z

No change:
don't send
out DV

Node y

cost to

	x	y	z
from x	∞	∞	∞
from y	2	0	1
from z	∞	∞	∞

cost to

	x	y	z

No change:
don't send
out DV

cost to

	x	y	z

No change:
don't send
out DV

Node z

cost to

	x	y	z
from x	∞	∞	∞
from y	∞	∞	∞
from z	7	1	0

cost to

	x	y	z
from x	0	2	7
from y	2	0	1
from z	3	1	0

cost to

	x	y	z

No change:
don't send
out DV

DONE

Node detects local link cost change

1. Updates routing info
2. Recalculates DV
3. If DV changes, notify neighbors

Good news travels fast

t_0 : y detects link-cost change, updates its DV, informs its neighbors

t_1 : z receives update from y, updates its table, computes new least cost to x, sends its neighbors its DV

t_2 : y receives z's update, updates its distance table. Y's least costs do not change, so y does not send a message to z

Bad news travels slow

Count to infinity problem

- 44 iterations before algorithm stabilizes

Intuitively

- when z tells y it has a path to x, y has no way of knowing that z is using y on its path

		cost to			
		Y	x	y	z
from	x	0	4	3	
	y	4	0	1	
	z	5	1	0	

→

		cost to			
		Y	x	y	z
from	x	0	4	3	
	y	6	0	1	
	z	5	1	0	

$$D_y(x) = \min\{c(y,x) + D_x(x), c(y,z) + D_z(x)\}$$
$$= \min\{60 + 0, 1 + 5\} = 6$$

→ Routing Loop

$$D_z(x) = \min\{c(z,x) + D_x(x), c(z,y) + D_y(x)\}$$
$$= \min\{50 + 0, 1 + 6\} = 7$$

→ Count-to-infinity

Problem arises because y still expects z can get to x with cost of 5

A proposed solution: poisoned reverse

If Z routes through Y to get to X

- Z tells Y its (Z's) distance to X is infinite (so Y won't route to X via Z)

		cost to			
		Y	x	y	z
from	x	0	4	5	
	y	4	0	1	
	z	∞	1	0	

$$D_y(x) = \min\{c(y,x)+D_x(x), c(y,z)+D_z(x)\}$$
$$= \min\{60+0, 1+\infty\} = 60$$

Q: Will this completely solve count to infinity problem?

- no, only for 2 node loops

Another proposed solution: hold time

- don't process route updates for period of time after route retraction
- ameliorates problem but does not solve

Distance vector routing summary

Easy to implement

- you will implement for hw9 :-)

Distributed

- x doesn't compute paths in isolation
- requires route info (path costs) computed by neighbors

Iterative

- x updates its DV whenever
 - local link costs change
 - DV update received from nbr

Asynchronous

- updates, exchanges happen asynchronously

Self-terminating

- x stops updating DV when no more changes received

Control Plane

LINK STATE VS. DISTANCE VECTOR ROUTING

Message complexity

n nodes
E links

Link state

- $O(nE)$ messages sent
 - every node floods its link state message out over every link in network to reach every node
- smaller messages
 - message size depends on the number of neighbors a node has
 - any link change requires a broadcast

Distance vector

- # of messages depends on convergence time which varies
 - nodes only exchange messages between neighbors
- larger routing update messages
 - message size is proportional to the number of nodes in the network
 - if link changes don't affect shortest path, no message exchange

Speed of convergence

n nodes
E links

Link state

- $\sum_{i=1}^{n-1} i = n(n+1)/2 = O(n^2)$
 - search through n-1 nodes to find min, recompute routes
 - search through n-2 nodes to find min, recompute routes
 - ...
- converges quickly but may have **oscillations**
 - route computation is centralized
 - a node stores a complete view of the network

Distance vector

- slow to converge and convergence time **varies**
 - route computation is distributed
- may be **routing loops**, **count-to-infinity** problem

What happens if router malfunctions?

n nodes
E links

Link state

- node can advertise **incorrect link cost**
- each node computes only its own table

Distance vector

- DV node can advertise **incorrect path cost**
- each node's DV used by others: errors propagate through network

Both have strengths and weaknesses.
One or the other is used in almost every network

Internet Routing

OVERVIEW

From graph algorithms to routing protocols

Need to address Internet reality

1. Internet is network of networks

- hierarchical structure
- routers **not all identical**
 - some routers connect different networks together
- each network admin may want to **control routing** in its own network

2. Scalability with billions of destinations

- don't all fit in one routing table
- can't exchange routing tables this big
 - would use all link capacity

Scalable routing on the Internet

Aggregate routers into regions called Autonomous Systems

Autonomous Systems (AS)

- aka **domain**
- network under **single administrative control**
 - company, university, ISP, ...
- **30,000+ ASes**: AT&T, IBM, Wesleyan ...
- each AS has a **unique 16-bit AS #**
 - Wesleyan: AS167
 - BBN: used to be AS1: was first org to get AS # then L3 later acquired

AS160	U-CHICAGO-AS - University of Chicago, US
AS161	TI-AS - Texas Instruments, Inc., US
AS162	DNIC-AS-00162 - Navy Network Information Center (NNIC), US
AS163	IBM-RESEARCH-AS - International Business Machines Corporation,
AS164	DNIC-AS-00164 - DoD Network Information Center, US
AS165	DNIC-AS-00165 - DoD Network Information Center, US
AS166	IDA-AS - Institute for Defense Analyses, US
AS167	WESLEYAN-AS - Wesleyan University, US
AS168	UMASS-AMHERST - University of Massachusetts, US
AS169	HANSCOM-NET-AS - Air Force Systems Networking, US

Hierarchical routing

2-level route propagation hierarchy

1. **intra AS routing protocol** between routers in same AS
 - aka intra domain routing protocol
 - aka interior gateway protocol
 - each AS selects its own

Focus is performance
2. **inter AS routing protocol** between gateway routers in different ASes
 - aka inter domain routing protocol
 - aka exterior gateway protocol
 - Internet-wide standard

Policy may dominate performance

Q: Can routers in different ASes run different intra AS routing protocol?

Hierarchical routing

Forwarding table

- **intra-AS** sets entries for internal dsts
- **inter-AS** & **intra-AS** sets entries for external dsts

Gateway router

- at edge of its own AS
- direct link to router in another AS
- perform inter-AS as well as intra-AS routing
- distributes results of inter-AS routing to other routers in AS

Example: set forwarding table in router 1d

AS1 learns (from inter-AS protocol)

- subnet **x** is reachable via AS3 (gateway 1c) but not via AS2

Router 1d learns (from intra-AS protocol)

- that its interface **y** is on least cost path to 1c.
- installs forwarding table entry **(x,y)**

Q: What if multiple ASes can be used to reach x?

INTERNET CONTROL MESSAGE PROTOCOL OVERVIEW

Internet Control Message Protocol (ICMP)

Used by hosts & routers to communicate network-level information

- error reporting
 - unreachable host, network, port, protocol
- echo request/reply
 - used by ping)
- network-layer above IP
 - ICMP msgs carried in IP pkts

ICMP message

- type, code plus first 8 bytes of IP pkt causing error

<u>Type</u>	<u>Code</u>	<u>Description</u>
0	0	echo reply (ping)
3	0	dest. network unreachable
3	1	dest host unreachable
3	2	dest protocol unreachable
3	3	dest port unreachable
3	6	dest network unknown
3	7	dest host unknown
4	0	source quench (congestion control - not used)
8	0	echo request (ping)
9	0	route advertisement
10	0	router discovery
11	0	TTL expired
12	0	bad IP header

Traceroute and ICMP

Source sends series of segments or packets to destination

- first set has TTL =1
- second set has TTL=2, etc.
- unlikely port number

When *n*th set arrives to *n*th router

- router discards and sends source ICMP message (type 11, code 0)
- ICMP message includes name of router & IP address

When ICMP msg arrives

- source records RTTs

Stopping criteria

TCP segment or UDP datagram eventually arrives at dst host

- dst returns ICMP “port unreachable” message
- source stops

Q: why can traceroute work with segments, datagrams, or packets?

ICMP traceroute

We're generating an ICMP echo request

Intermediate routers

- respond with ICMP ttl expired

Final destination

- responds with ICMP echo reply

NETWORK PROGRAMMING

BIT-WISE OPERATIONS IN PYTHON

Bit-wise operations on variables

$x \ll y$

- returns x with bits shifted to left by y places
 - new bits on right-hand-side are zeros
 - same as multiplying x by 2^y

$x \gg y$

- returns x with bits shifted to right by y places
 - same as dividing x by 2^y

$x \& y$

- does a bitwise and
 - each bit of output is 1 if corresponding bit of x AND of y is 1, otherwise 0

$\sim x$

- returns complement of x
 - number you get by switching each 1 for 0 and each 0 for 1

E.g.,

- use to pack `ip_version` and `ip header length` into 8 bits
